Heat transfer in porous medium

UNIVERSIDAD DE MEDELLIN

- Heat transfer by conduction, advection and mechanical dispersion
- Temperature evaluated at:
 - 2148 days
 - 4262 days

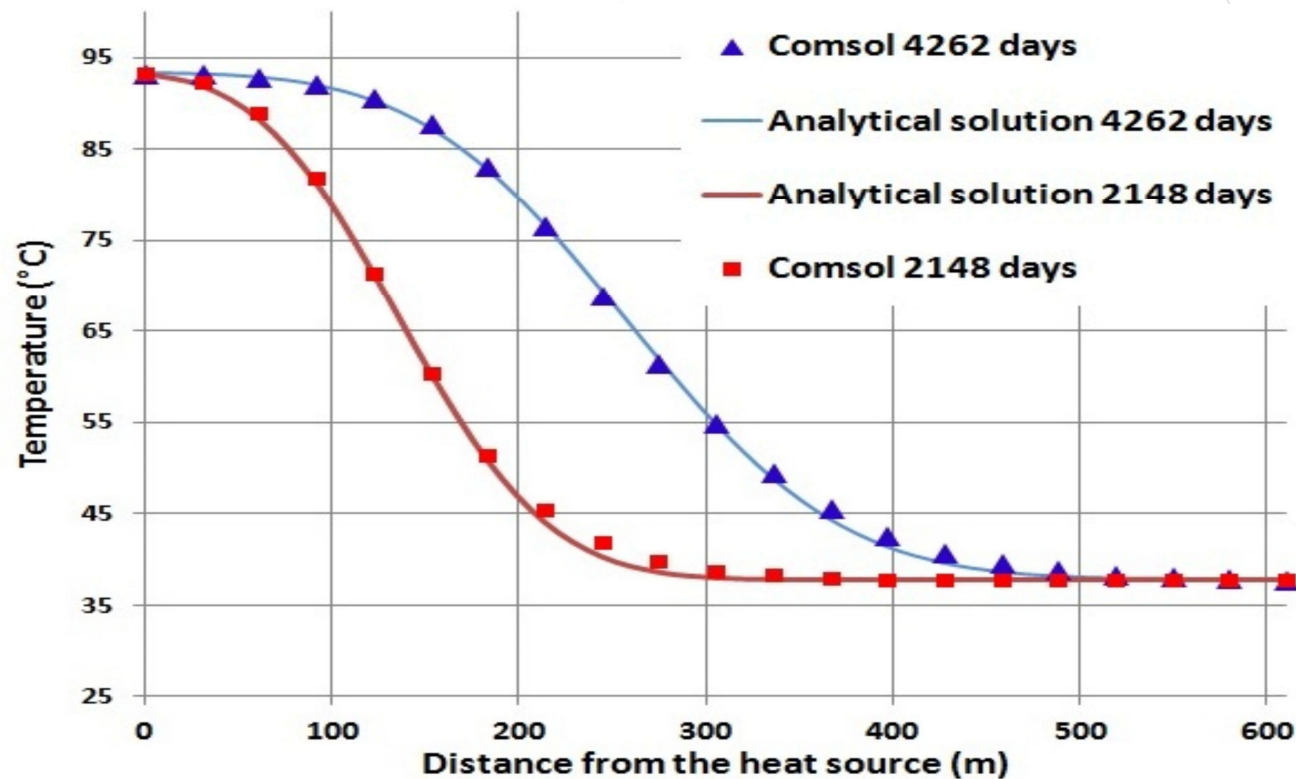

Heat transfer in porous medium

UNIVERSIDAD DE MEDELLIN

● Analytical and numerical results

UNIVERSIDAD DE MEDELLIN

Heat transfer in fractured porous medium

- Heat transfer by conduction into the matrix and advection along the fracture (no mechanical dispersion)
- Temperature evaluated at 5000 s and 10000 s

UNIVERSIDAD DE MEDELLIN

Heat transfer in fractured porous medium

- Fracture is represented by an equivalent porous medium (EPM)
 - Mesh size limitation (2D and smaller domain)
 - Equivalent hydraulic conductivity for the fracture zone:

$$K_f = \frac{\gamma(2b)^2}{12\mu}$$

- K_f : Fracture zone hydraulic conductivity (m/s)
- b : Fracture aperture (m)
- μ : Water dynamic viscosity (Pa·s)
- γ : Water specific weight (N/m³)

UNIVERSIDAD DE MEDELLIN

Heat transfer in fractured porous medium

- Temperature boundary condition is applied to a line

B

C

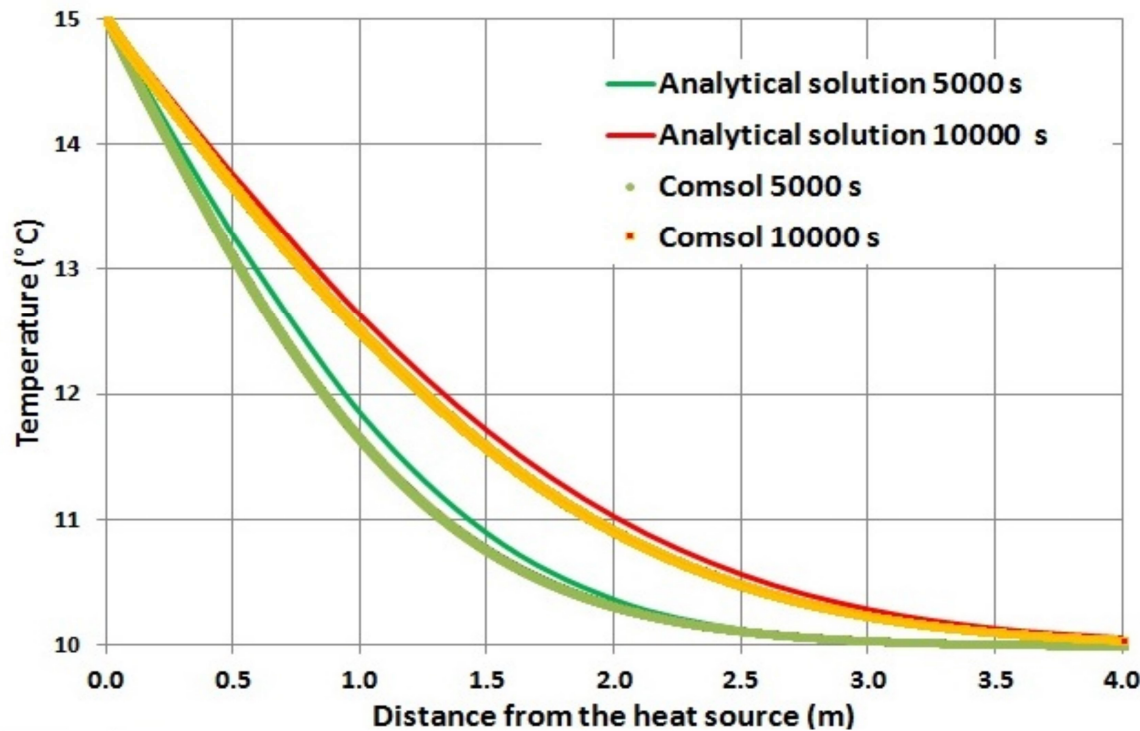

Fracture zone width: 3×10^{-4} m
where constant temperature is applied

UNIVERSIDAD DE MEDELLIN

Heat transfer in fractured porous medium

● Temperature along the fracture

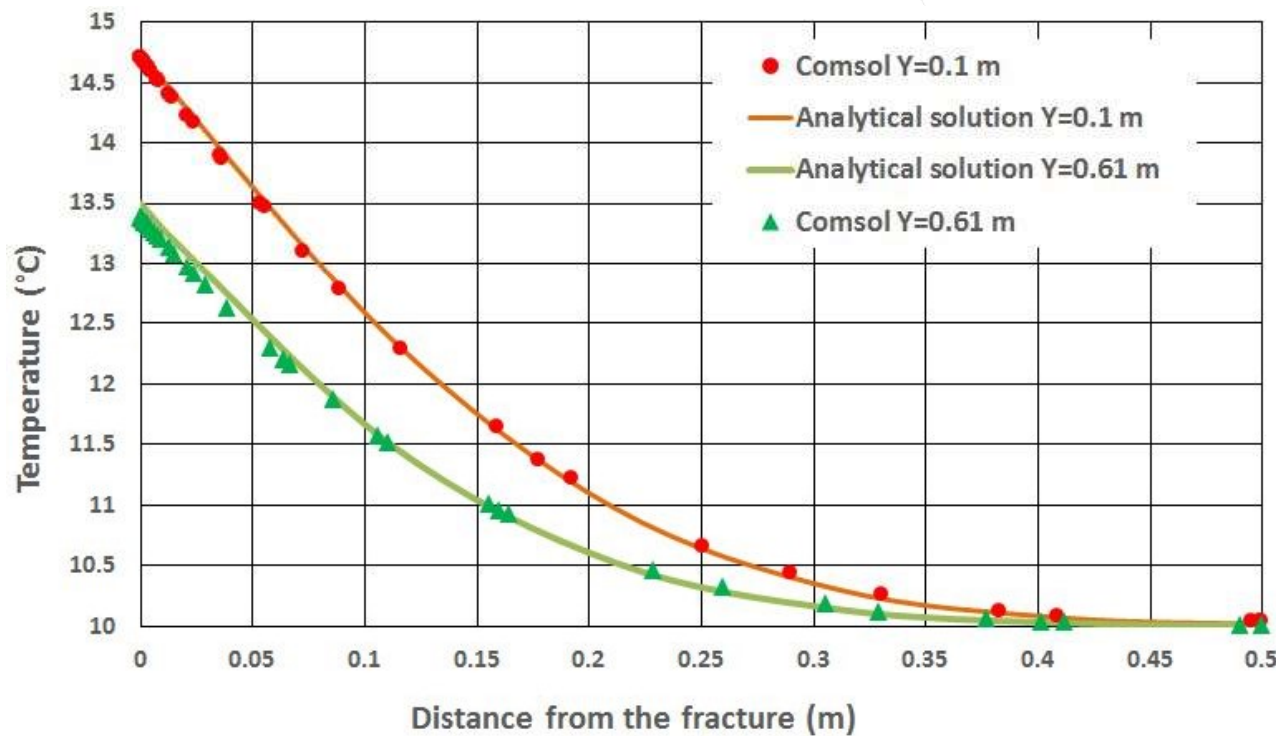

UNIVERSIDAD DE MEDELLIN

Heat transfer in fractured porous medium

● Temperature in the porous matrix

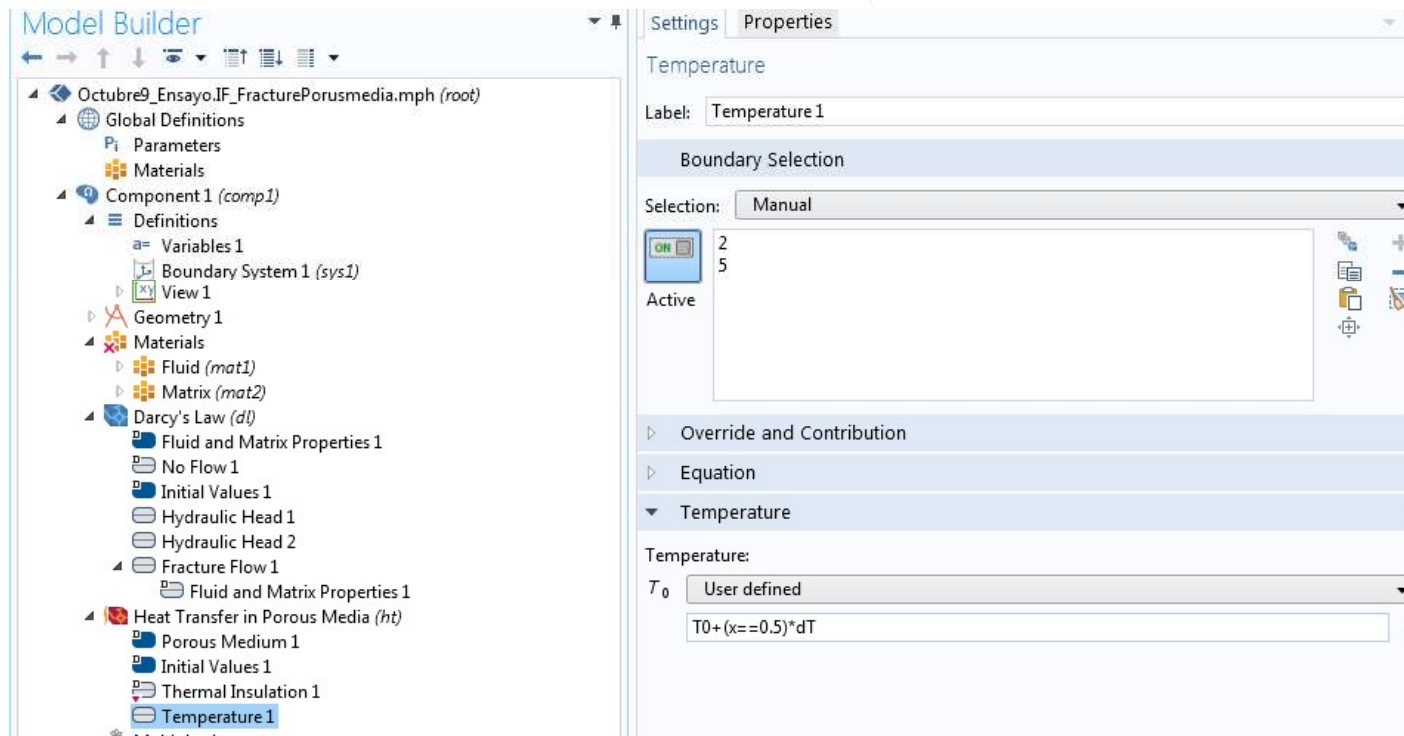

UNIVERSIDAD DE MEDELLIN

Heat transfer in fractured porous medium

- Temperature boundary condition to the discrete fracture

UNIVERSIDAD DE MEDELLIN

Conclusions

- **Good numerical approximations for heat transfer in the porous medium and along a fracture were obtained**
- **A limitation of the heat transfer in porous medium Comsol module has been identified**
 - **Among the boundary condition options, there is not the possibility to set a temperature boundary condition to a point**
 - **The discrete fracture is independent of the matrix (nodes are not common or superposed, as in HGS)**
